# Prediction of Immunotherapy response in NSCLC based on RW evidence and radiomic features

Author: Mariagrazia Monteleone 952133

Advisor: Prof. Elena De Momi

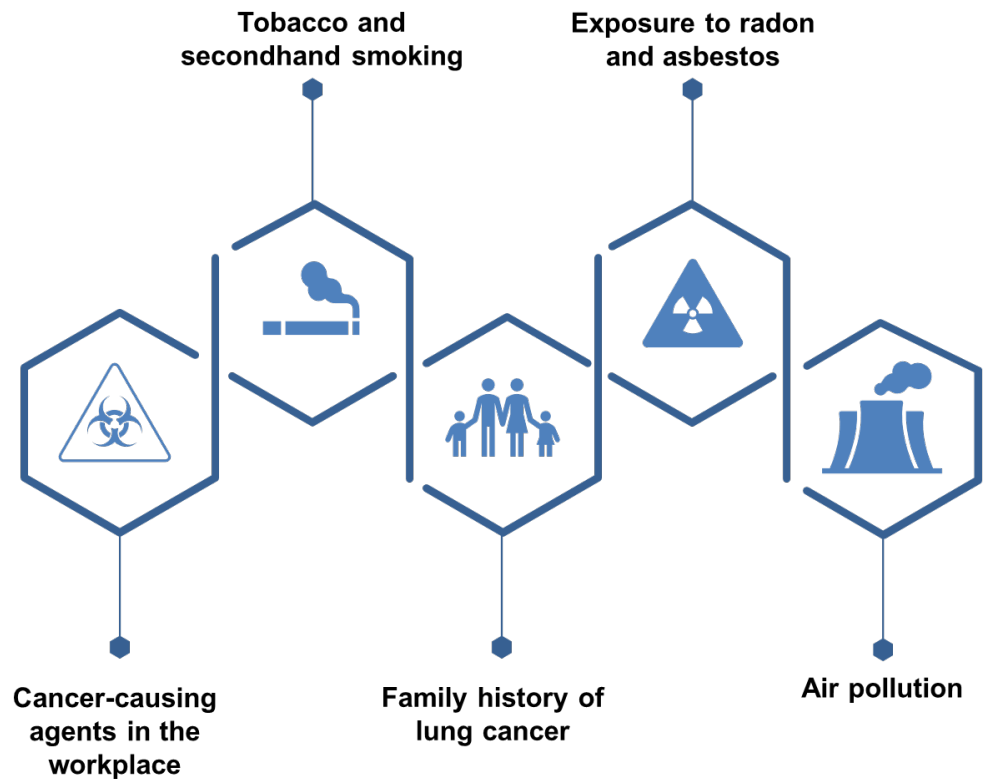

Co-advisor: Dott.ssa Arsela Prelaj M.D., Dott. Aldo Marzullo, Prof. Alessandra Laura Giulia Pedrocchi, Prof. Giuseppe Baselli

Academic Year: 2021-22

Lung cancer, with the most frequent histology of Non-Small Cells Lung Cancer (NSCLC), is still on top of the rankings as the leading cause of tumor-related deaths (H. Sung et al., 2021).

- Only in 2020:
- 2.2 million new estimated cases
  - 1.8 million deaths

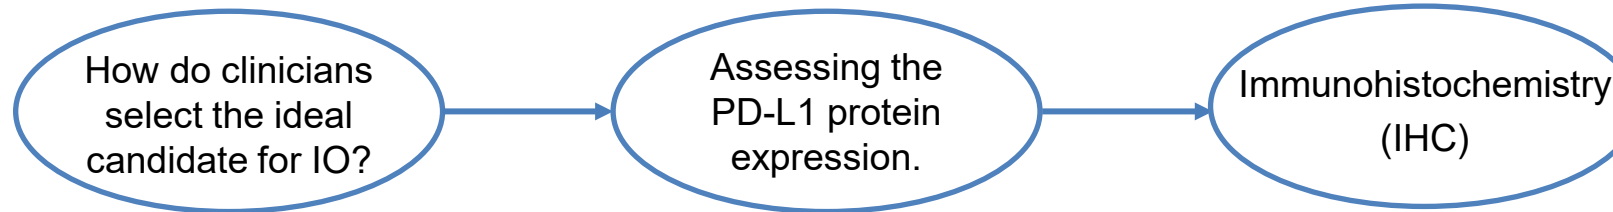

Immunotherapy (IO) completely changed the NSCLC landscape reaching a median survival for a median OS of 24 months compared to the 12 months obtained with chemotherapy (CT) alone (H. Borghaei et al., 2019).

Some Patients Who respond to IO continue with the Duration of Response over 5-years:

**This Never happened before**

Only a small percentage of patients benefits from IO making the selection of the ideal candidate very challenging.

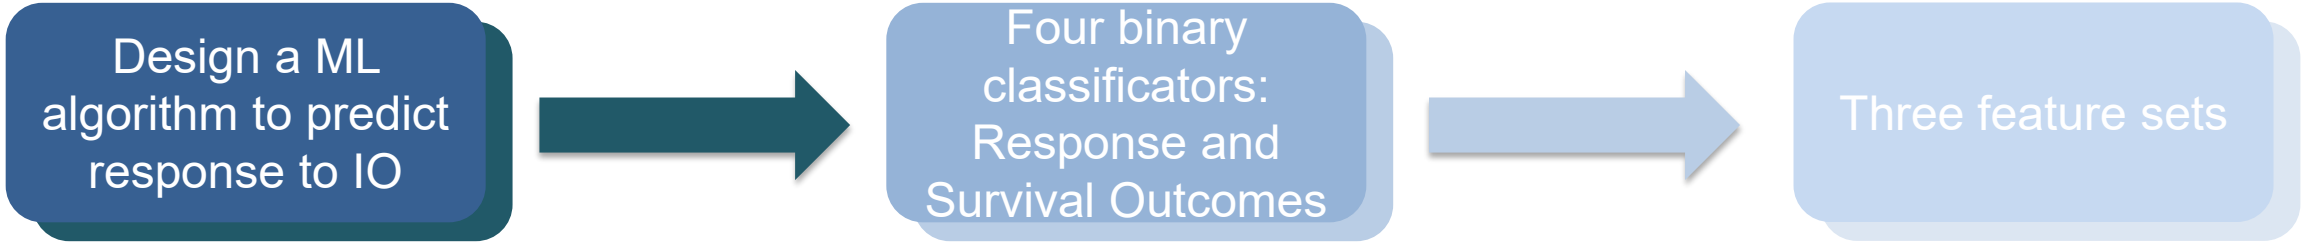

- ➡ Tumour Mutational Burden (TMB) (KEYNOTE 158 , A. Marabelle et al., 2020)
- ➡ Tumour Infiltration Lymphocytes (TILs) (D.Q. Zeng et al.,2016)
- ➡ Neutrophil to Lymphocyte Ratio (NLR) (S. Diem et al.,2017)
- ➡ Tumour Microenvironment (TME) (Huang et al., 2020)

**After 10 years of basic & translational researches, PD-L1 remains the only confirmed biomarker approved for clinical practice for NSCLC patients.**

An alternative solution might be to use a Machine Learning (ML) approach to exploit different type of information to predict the treatment outcome.

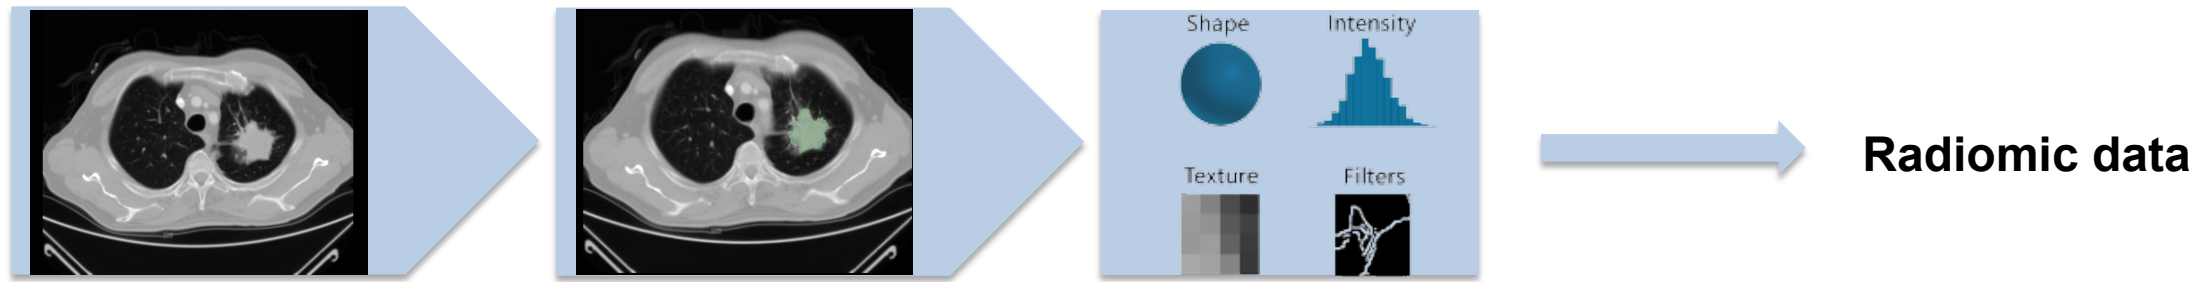

- ➡ Real World Evidence set (RW)
- ➡ Radiomics set (RD)
- ➡ Combination Set (RW + RD)

Thanks to the implementation of the Electronic Health Record (EHR), a large set of patient information are available in clinical institution databases.

Radiomics is a quantitative approach to medical imaging (J. E. v. Timmeren et al.,2020) .

The study was conducted on 184 patients with IO, alone or in combination with chemotherapy, at the National Cancer Institute of Milan between 2015 and 2020 under the APOLLO study.

# Materials and Methods: Image and Features Processing

## RW and RD features

**25 Real Evidence features (RW)**  
**5 Radiomics features (RD)**

## Disease Control Rate (DCR)

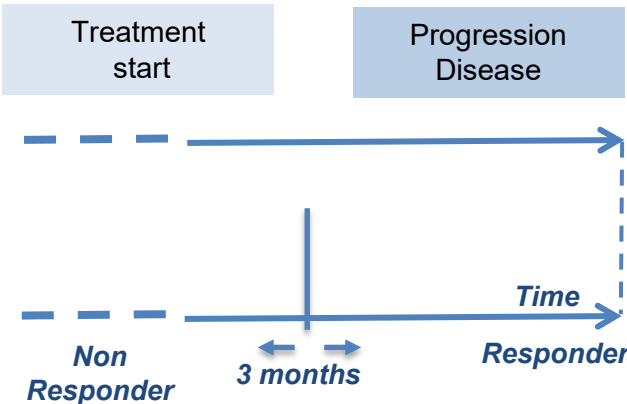

Percentage of patients whose disease shrinks or remains stable over a certain time period according to the geometric criteria illustrated by the RECIST guidelines (S. Litière et al.,2017)

**Responder**

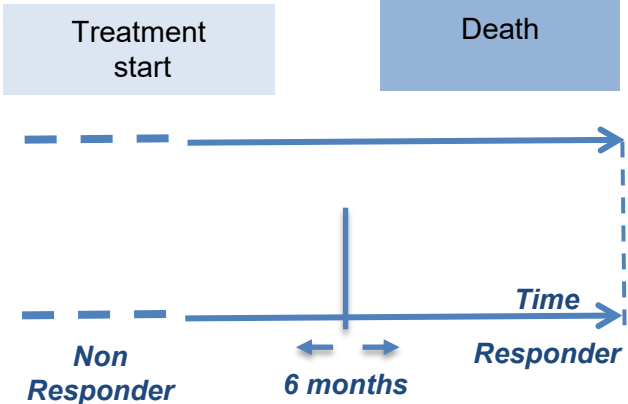

**Non-Responder**

## Progression-Free Survival (PFS)

## Overall Survival (OS)

01

**K-Nearest Neighbors (KNN)**

02

**Logistic Regression (LR)**

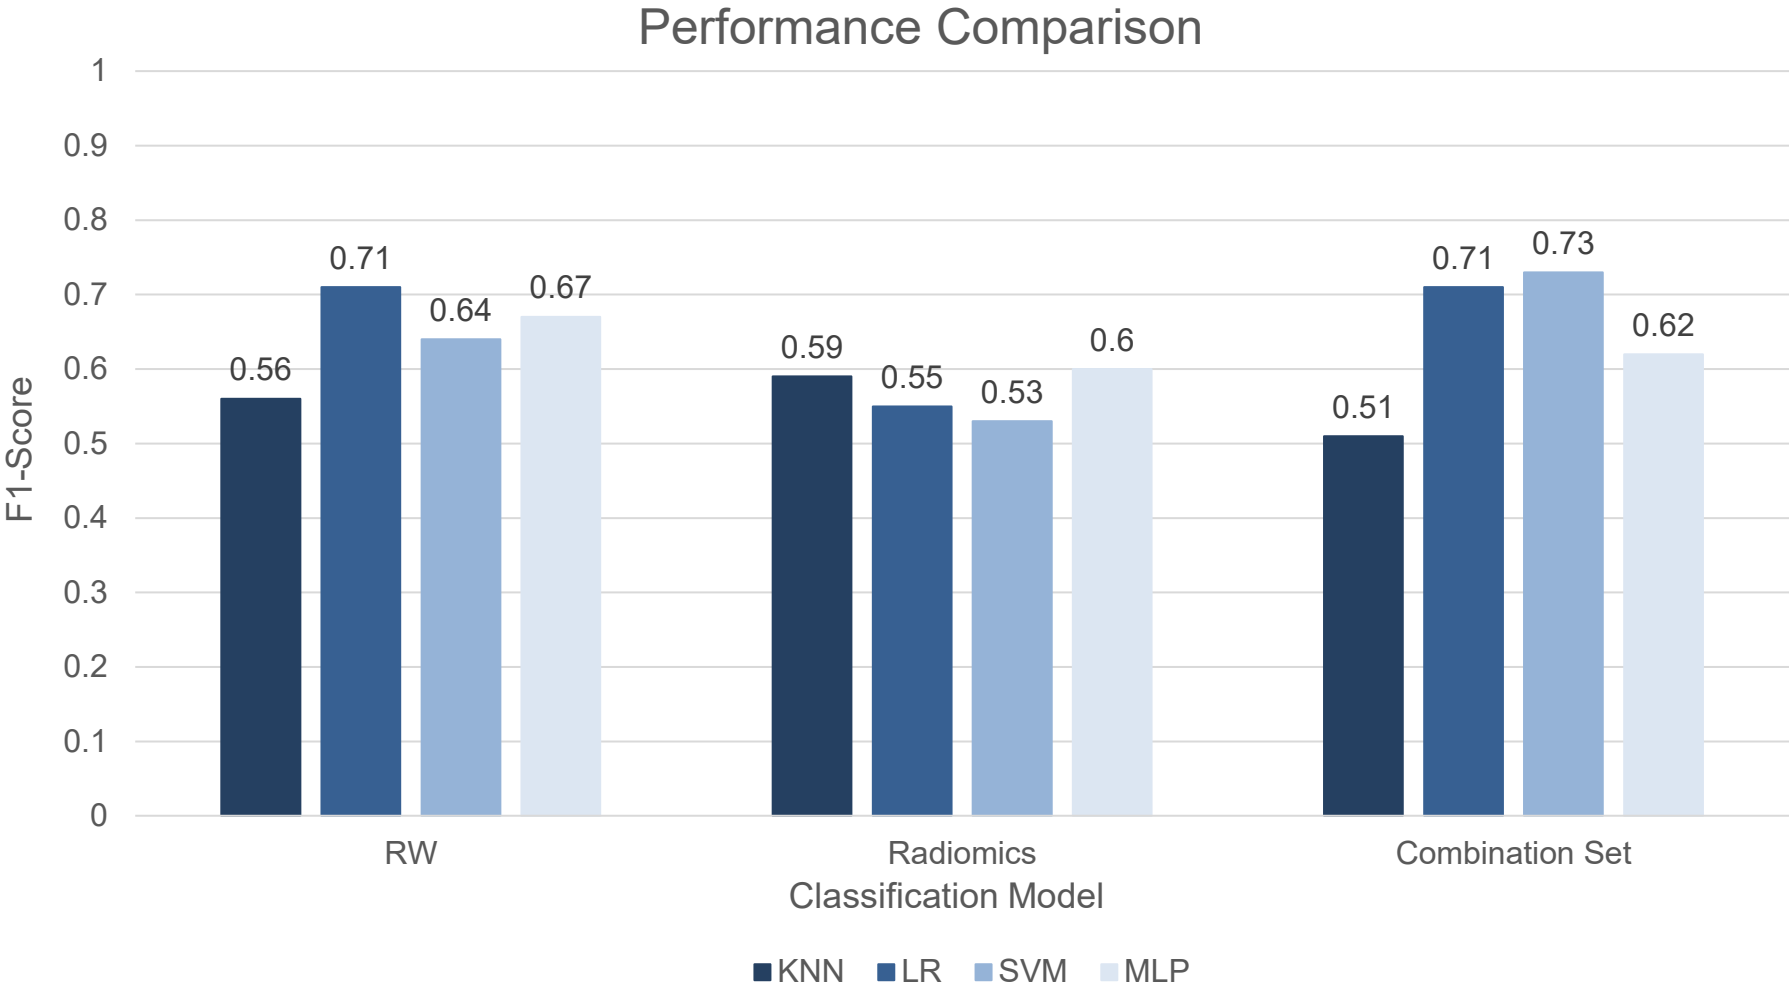

03

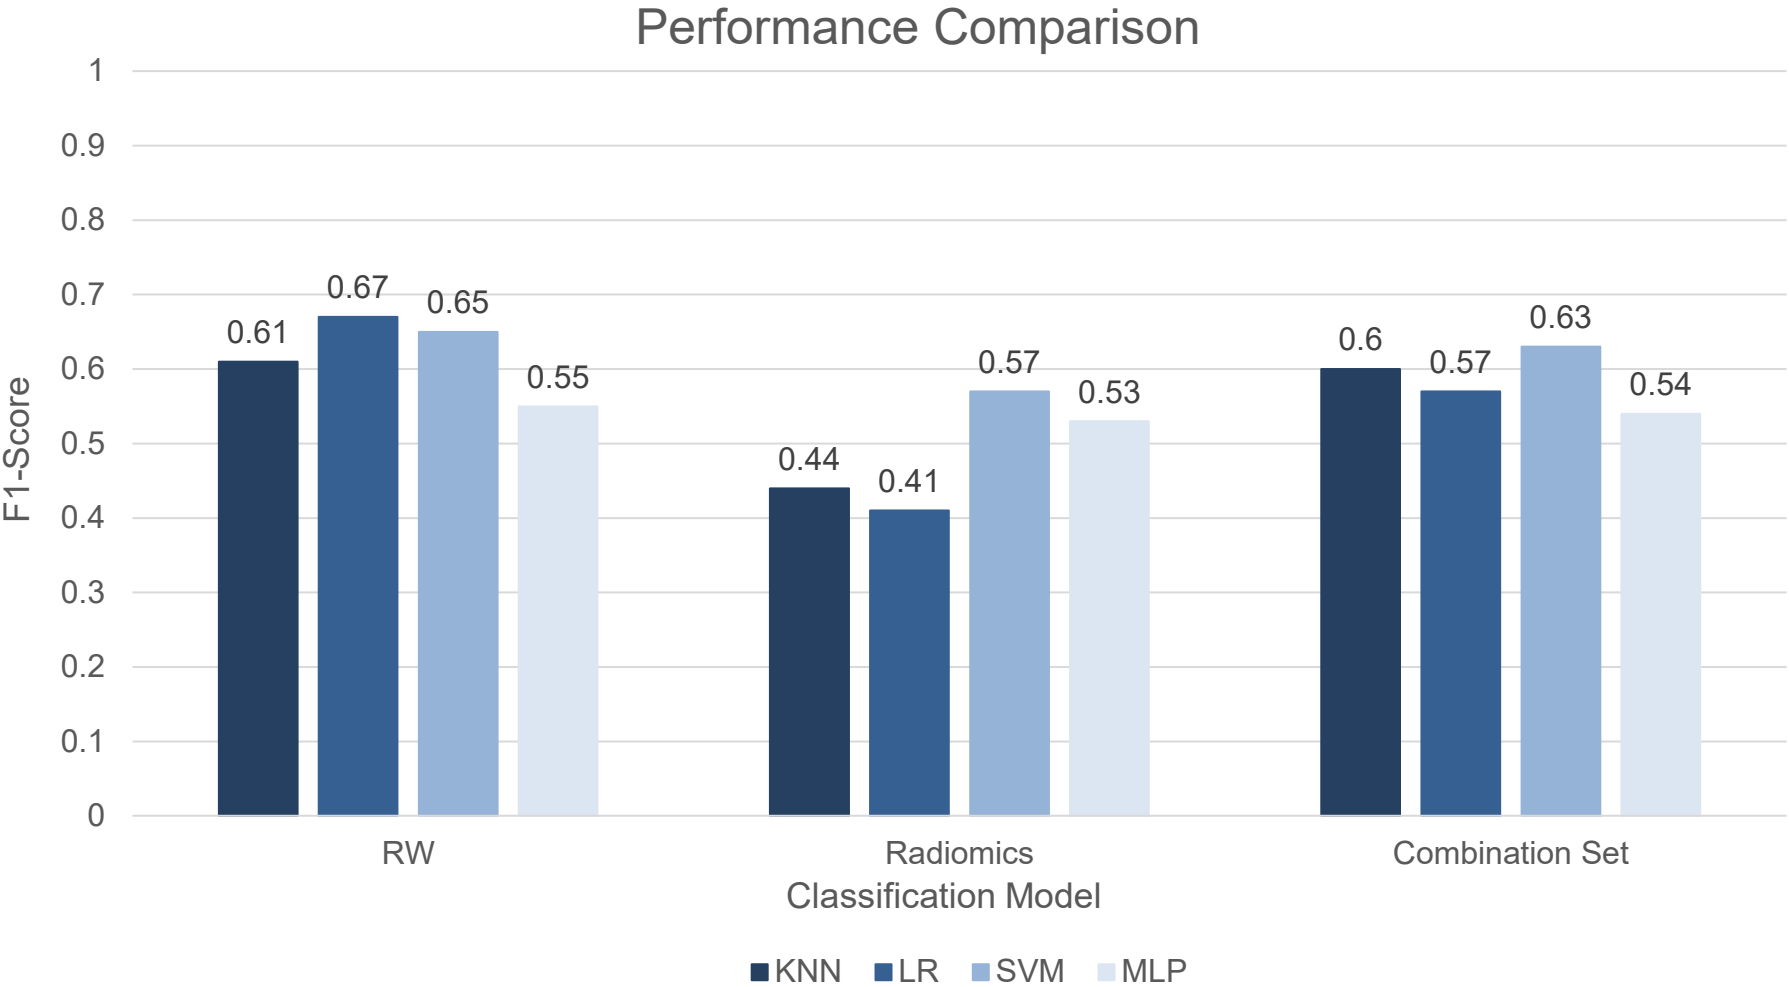

**Support Vector Machine (SVM)**

04

**Multi-Layer Perceptron (MLP)**

- All the models were tuned by *GridSearch Cross Validation* to find the best hyperparameters
  - 70% data for training and 30% for external validation
  - On the training set was implemented a K-fold Cross-Validation ( $k = 5$ )

# Experimental Results: Feature Importance Analysis for Disease Control Rate

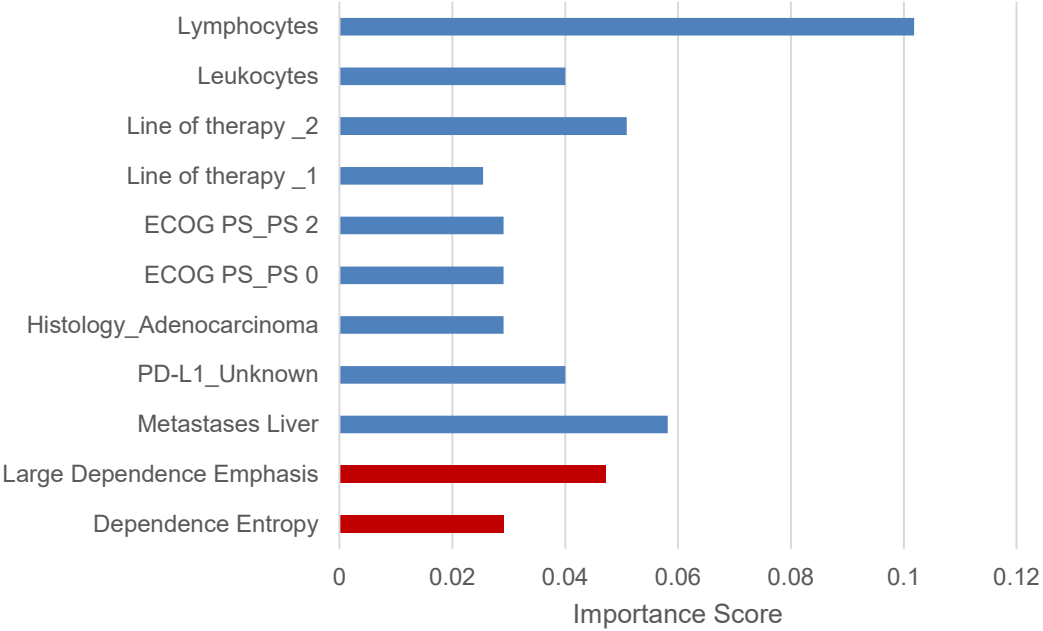

The feature importance analysis is presented for the best results obtained on the **DCR** outcome for the **LR** and **SVM** trained on the combination set (**RW** + **RD**).

## Logistic Regression

## Support Vector Machine

- ➔ Overall, ML algorithms showed to better perform using Real World Evidence features. However, the results obtained from the combination set suggest that the integration of different data set (RW data + radiomics) need to be further exploit.
- ➔ Radiomic features seem have a greater importance when they are implied to predict response to immunotherapy rather than survival outcomes.

## Future Developments:

- Include more patients' data
- Set a clear image acquisition protocol
- Assure a higher variability in terms of radiomic features

Thanks for your time and attention
